

Your Paper Title: A Concise Description of Your Idea

Your Name

Abstract—This document is a blank research-paper template for a graduate course final exam. Replace this paragraph with a self-contained summary of your own paper: the problem and its importance, the gap in existing work, the central idea of your approach, and the evidence supporting your conclusion. State what was actually evaluated and what remains a proposal. Identify the setting in which the problem arises and the assumptions that define the scope of the study. Briefly describe the evaluation protocol, the comparison used to assess the idea, and the main observation supported by the evidence. Explain the practical meaning of that observation without overstating its generality. Close with the most important limitation and the question that remains open. Keep the abstract understandable without requiring the reader to consult figures, equations, or references. All figures, table entries, equations, and references in this template are illustrative placeholders, not research findings.

I. INTRODUCTION

Context and motivation. Introduce the research area in your own words. Describe a concrete problem, who encounters it, and why solving it would matter. Define the scope so that a reader outside your immediate specialty can follow the paper. Use a field survey to orient the reader [1], and a source on the application to support the motivation [2]. These citations, like all references in this template, are fictional examples of citation roles and must be replaced with verified publications.

Describe a representative situation in which the problem becomes visible. Explain what information is available, what decision or output is needed, and what makes the task difficult.

Gap and research question. Explain what existing approaches do not yet address. Support this gap with real sources and formulate a specific, answerable research question. Avoid claims of novelty that have not been checked against prior work. Anchor the comparison in a foundational approach [3] and a relevant alternative [4]. Cite the work at the point where you discuss its scope; a citation alone does not establish a limitation.

Distinguish the practical challenge from the scientific question you intend to investigate. Clarify whether the gap concerns a missing capability, an untested assumption, or an insufficient explanation of existing behavior. State the conditions under which answering your question would be useful, and identify aspects of the broader problem that fall outside this paper.

Key idea. Summarize your proposed approach in a few sentences. Explain why the idea could address the gap

DUMMY FIGURE: THE KEY IDEA

The challenge $\longrightarrow$ Your insight

What should the reader remember?

Fig. 1. Visual hook. Replace with a compelling example that shows the problem and your central insight at a glance. This is a placeholder, not an experimental result.

and identify the assumption on which it depends. Figure 1 highlights the central idea or motivating example. Figure 2 provides a full-width overview of the method.

Explain the intuition connecting the proposed mechanism to the identified gap. Contrast this intuition with a reasonable alternative and describe the evidence needed to distinguish the two explanations. Introduce only the technical terms necessary to understand the idea here; reserve detailed notation and implementation choices for the later sections.

Evaluation scope. Outline how the paper will examine its central claim. Identify the types of comparisons, examples, and controlled changes needed for that purpose. Explain how the evaluation relates to the motivating situation and what it cannot establish. If the work is a proposal, clearly distinguish the planned evaluation from any analysis already completed.

Contributions. Replace the following items with concrete contributions supported by the paper:

- A clearly scoped problem or research question: [replace].
- An approach or analysis addressing that question: [replace].
- Evidence and limitations from an appropriate evaluation: [replace].

The remainder of this paper reviews related work, defines the problem, describes the method and evaluation, and discusses limitations.

II. RELATED WORK

A. Research Direction A

Group relevant prior studies by the ideas they share. Explain the problem they solve, their key assumptions, and the evidence they provide. Start with a foundational method [3] and use a survey to explain how that method fits into the wider field [1]. Replace these fictional entries with real papers you have read.

DUMMY FIGURE: METHOD OVERVIEW

Input $\longrightarrow$ Your Method $\longrightarrow$ Output

Replace with your own pipeline or concept diagram.

Fig. 2. Placeholder overview. Describe the inputs, the main components, and the outputs of your own approach. No research result is shown.

Describe the assumptions that make this family of methods suitable for its target setting. Identify the information it requires and the type of output it produces. When discussing a shortcoming, distinguish a limitation stated by the original authors from your own interpretation. Explain the evidence behind that interpretation and avoid extrapolating beyond the study’s scope.

B. Research Direction B

Describe an alternative family of approaches and compare its strengths and limitations with the first group. Use consistent comparison criteria, such as required inputs, applicability, or evaluation conditions. Use the alternative-method citation for the approach itself [4] and the representation citation for the information it operates on [5]. This separation demonstrates how different sources can support distinct parts of a comparison.

Compare the two directions under the same criteria. A method that uses additional input information may not be directly comparable to one designed for a more constrained setting. Explain such differences before discussing performance. If the available studies use different protocols, describe those differences rather than treating their reported values as equivalent.

C. Hybrid Approaches and Shared Components

Some papers combine ideas from multiple research directions. Use a source on a hybrid approach to discuss that relationship [6], then identify the components it shares with earlier work [3], [4]. Explain whether the combination changes the assumptions, the computational requirements, or the type of problem that can be addressed.

When your paper reuses a representation or solver, acknowledge those dependencies explicitly [5], [7]. Distinguish the origin of a method from the implementation used in your experiments. A software reference [8] credits the implementation, but it does not replace a citation to the underlying scientific idea.

D. Evaluation Practices

Review how related studies evaluate their claims. Dataset documentation and metric definitions serve different purposes [9], [10]: the former describes the evaluation material, while the latter explains what a reported number means. Discuss whether the protocol measures the capability that your paper aims to improve.

Identify the most relevant baseline [11] and explain why it is an informative comparator. Use guidance on repeated trials and controlled experiments to motivate your evaluation design [12], [13]. Replace these placeholders with sources appropriate to your discipline; the template does not assume that one protocol fits every research problem.

E. Positioning of This Work

Explain precisely how your question or approach relates to the reviewed work. Identify what you reuse and what you change. A difference in method does not by itself establish an improvement; state what evidence would be needed to support that claim. Relate the proposed contribution to the closest method, rather than only to a broad survey [6]. State which previously studied limitation your evaluation will address [14], and which questions remain outside the paper. This paragraph should lead directly to the problem formulation and the comparisons used later in the manuscript.

III. PROBLEM FORMULATION

Define the task, the inputs available to your method, and the output you want to produce. State the assumptions and constraints explicitly. Introduce notation before using it, and remove mathematics that does not help explain your particular problem.

For formatting purposes only, let $x \in \mathcal{X}$ denote an input and $\hat{y} \in \mathcal{Y}$ an estimated output. A generic mapping is

$$\hat{y} = f_{\theta}(x), \quad (1)$$

where θ denotes the parameters of the mapping. Replace Eq. (1) and these definitions with your own formulation. Specify how success will be measured and under which conditions.

IV. PROPOSED METHOD

A. Overview

Describe the complete procedure from input to output. Refer to Fig. 2 and explain the role of each component. Separate your own contribution from standard components or reused methods.

B. Main Component

Explain the central mechanism in enough detail for another student to understand and implement it. Define any parameters, dependencies, and design choices. Explain why those choices follow from the problem. If the component uses an

existing representation, cite its source when introducing the representation [5]. State what is retained and what is changed instead of presenting reused elements as new work.

If an optimization objective is relevant, use the following layout as an example and replace the expression with your actual objective:

$$\theta^* = \arg \min_{\theta} \frac{1}{N} \sum_{i=1}^N \ell(f_{\theta}(x_i), y_i). \quad (2)$$

Here, N is the number of examples, (x_i, y_i) is an input–target pair, and ℓ is a loss function. This generic equation is not a proposed research contribution and may be deleted. When adopting an established objective or solver, cite the relevant methodological source [7]. Explain how the adopted method is instantiated for your variables, constraints, and stopping criterion.

C. Implementation Details

Report the settings needed to reproduce your method, such as preprocessing, parameter selection, software dependencies, and computational resources. For a conceptual proposal, distinguish planned steps from implemented ones. Cite the software framework actually used [8] and report its version and relevant configuration in your final paper. Replace this placeholder with the library’s recommended citation or a stable release reference, as appropriate.

D. Component Design and Information Flow

Figure 3 provides a closer view of a single component. Use this figure to explain an internal mechanism that would be too detailed for the system overview. Name the information entering each stage, describe the operation applied to it, and specify what is passed to the next stage. Keep terminology consistent between the diagram, equations, and text.

Explain how intermediate representations are constructed. Describe whether they are computed independently for each input or depend on earlier inputs. If the method maintains a state, define its initialization and update rule. If it combines multiple sources of information, explain how their relative influence is determined. State what happens when an expected input is unavailable, incomplete, or outside the assumed operating range.

Describe the interface between your proposed component and the rest of the system. A reader should be able to distinguish the component’s inputs and outputs from implementation conveniences. Identify any quantities that are available during development but unavailable at evaluation time. Explain how the evaluation prevents information from the test set from influencing the method or its settings.

E. Design Rationale and Alternatives

For each major design decision, describe the alternative that a reasonable reader might consider. Explain why the selected option is appropriate for the stated problem. These explanations should be testable where possible: identify which experimental comparison could support or weaken each claim. Avoid presenting a convenient implementation choice as a demonstrated scientific advantage.

Fig. 3. Mechanism diagram placeholder. Show how one component works internally, including intermediate representations and operations. This figure complements the full-system overview in Fig. 2.

F. Reproducibility and Computational Cost

Describe the software environment, input preparation, initialization, termination criteria, and sources of randomness. Report how settings are selected and which settings remain fixed across experiments. Distinguish one-time preparation costs from per-input costs, and specify whether reported timing includes loading data and producing the final output.

Explain the expected trade-off between task performance, computational cost, and complexity. For example, an additional component may require more memory or processing time. State the conditions under which that trade-off would be acceptable, and evaluate it under a documented protocol [12]. For a proposal, describe how cost would be measured instead of inventing timing or memory values.

V. EXPERIMENTS AND RESULTS

A. Evaluation Questions and Setup

State which claim each experiment tests. Describe the data or study materials, inclusion criteria, baselines, evaluation metrics, and procedure. Explain how comparisons are made fair and how uncertainty is assessed. Report actual experimental conditions instead of inventing missing details.

Describe the origin and relevant properties of the evaluation material. Explain how development and evaluation subsets are separated, including any grouping needed to prevent closely related examples from appearing in both. State the scope of the evaluation: what variation is represented and which operating conditions are absent. If the study uses simulations or constructed examples, explain how those conditions relate to the intended application and where the comparison may break down. Cite the dataset or study-material source here [9]. Record the release, subset, and split used so that the reference identifies the resource and the text identifies your specific use of it.

Define each evaluation metric before interpreting its values. Give its units, preferred direction, aggregation rule, and treatment of failed or missing outputs. Explain why the chosen metrics reflect the research question. If different metrics emphasize different aspects of performance, state how those differences will inform the interpretation rather than selecting only the metric that favors the proposed

approach. Use the metric reference to credit an adopted definition [10]. Describe any deviation from that definition and its effect on comparability.

B. Baselines and Comparison Protocol

Select baselines that test the contribution you actually claim. Include a simple reference method where useful, and explain the relevance of more complex alternatives. Document whether baseline implementations are reused or reimplemented. Specify the settings used for each method and describe how the development budget is made comparable across approaches. Cite the baseline’s original method [11] and any implementation dependency separately [8]. A comparison should make clear both what was evaluated and how it was implemented.

State how many independent runs or evaluation units are used and why. Describe how variation is summarized and identify the unit over which an uncertainty interval is computed. Reference a suitable reproducibility protocol when one informs the design [12], while reporting your actual settings rather than relying on the citation for those details.

C. Quantitative Evaluation

Table I demonstrates a compact results table. All entries are intentionally unfilled; dashes do not mean zero. Replace column headings with task-specific metrics and units, and indicate whether larger or smaller values are preferred.

Describe the main observation supported by your measurements. Separate observations from explanations, and avoid claiming an improvement without appropriate evidence. If experiments have not been conducted, label this section as an evaluation plan and do not present anticipated outcomes as results.

D. Qualitative Evaluation

Use examples to explain behavior that a single numerical metric cannot capture. Figure 4 provides a two-panel placeholder. Include informative captions, matched conditions, and both successful and unsuccessful cases where relevant.

E. Component Ablation

Table II provides a component-removal study. Define a common reference configuration and remove one component at a time. Keep the input data, evaluation protocol, and unrelated settings fixed. Explain what replaces a disabled component so that each variant remains a valid method rather than a broken implementation. Use an experimental-design reference to motivate the controlled comparison where relevant [13]. Explain how the design separates the effect of the component from changes in the evaluation procedure.

Interpret each comparison in terms of the component’s intended role. Consider whether a change could arise from a different computational budget or training procedure rather than the component itself. If the two components interact, discuss what can be learned by removing both. Do not describe a component as necessary or beneficial until the measured results support that conclusion.

TABLE I

PLACEHOLDER RESULTS. ALL DASHES MEAN “NOT MEASURED.”
REPLACE METHOD NAMES, METRIC HEADINGS, AND ENTRIES WITH
ACTUAL RESULTS.

Method	Metric A	Metric B
Baseline A	—	—
Baseline B	—	—
Your method	—	—

Fig. 4. Placeholder qualitative comparison. Replace both panels with your own examples and explain the relevant differences. These empty panels do not represent experimental evidence.

TABLE II

COMPONENT ABLATION PLACEHOLDER. A AND B ARE GENERIC
COMPONENTS; ALL METRIC ENTRIES ARE UNMEASURED.

Configuration	A	B	Metric
Full method	On	On	—
Without A	Off	On	—
Without B	On	Off	—
Without A and B	Off	Off	—

F. Design-Choice Ablation

Table III illustrates a complementary comparison of alternative design choices. Unlike removing a component, this study changes how a component operates. Specify one choice at a time and hold the rest of the configuration fixed. Replace the generic options with meaningful alternatives for your method, such as an aggregation rule or representation. Link these alternatives to the method literature [5], [6] so that the reader understands why they are meaningful choices to test.

Report both the task metric and a relevant resource cost. Explain whether an apparent improvement requires additional computation, memory, or access to information. State the selection criterion before examining the test results, and use development data to choose a final configuration. Discuss whether multiple alternatives offer different, reasonable trade-offs.

G. Sensitivity and Operating Range

Figure 5 provides a plot layout for a parameter sweep or robustness study. Its axes are intentionally empty; the figure contains no fabricated performance curve. Replace the labels with a named parameter and a defined metric, add units and values, and plot actual observations. Indicate uncertainty when repeated measurements are available. If an established robustness protocol guides the sweep, cite it at this point [15] and specify which parts of the protocol you follow.

TABLE III

DESIGN-CHOICE ABLATION PLACEHOLDER. VARY ONE DESIGN CHOICE AND COMPARE PERFORMANCE AND COST. DASHES DENOTE UNMEASURED QUANTITIES.

Design choice	Task metric	Cost
Reference option	—	—
Alternative A	—	—
Alternative B	—	—
Alternative C	—	—

Fig. 5. Sensitivity or robustness plot placeholder. Use the horizontal axis for a parameter or operating condition and the vertical axis for a measured metric. Add actual scales, observations, and uncertainty.

Choose a range that tests the operating assumptions of the method. Explain how the sampled settings were selected and why they are relevant to the intended application. Hold unrelated factors fixed, and report all tested settings rather than only a favorable subset. Identify any region where the method fails to produce a valid output and show how such failures are represented in the analysis.

H. Failure Cases and Summary of Evidence

Describe unsuccessful cases alongside successful ones. Connect each failure to a specific assumption or intermediate behavior, and distinguish an observed pattern from a speculative explanation. State what additional measurement would help identify the cause. Avoid using a few selected examples to claim a general failure rate.

Close the evaluation by returning to its original questions. State which claims are supported, which remain uncertain, and which were not tested. Explain how the quantitative comparisons, qualitative examples, ablations, and sensitivity analysis complement one another. This synthesis should reflect your collected evidence rather than repeat a list of figure and table captions.

VI. DISCUSSION AND LIMITATIONS

Interpret your findings in relation to the research question and prior work. Discuss alternative explanations, failure cases, and limits of the data and evaluation. Address ethical considerations where relevant, and identify a concrete next step for resolving the most important limitation.

A. Scope and Generalization

Explain how the study’s conditions differ from the setting in which the method might ultimately be used. Identify assumptions about inputs, available resources, and user behavior that were not directly evaluated. Discuss whether the observed evidence could plausibly transfer to other conditions and describe the additional study needed to test that transfer. Do not treat a limited evaluation as proof of general applicability. Relate observed failures to the robustness literature [15] and to documented limits of similar approaches [14]. Distinguish a limitation supported by those sources from a limitation demonstrated by your own study; neither should be substituted for the other.

B. Practical Considerations and Future Work

Consider the cost of collecting inputs, maintaining the system, and interpreting its outputs. Relate practical constraints to the motivating application [2]. Where relevant, discuss consequences of failure and the limits of deployment evidence [14], using sources that specifically address those issues in your research setting.

Prioritize one or two follow-up studies. Explain which unresolved question each study addresses, what evidence it would collect, and how that evidence could change the present conclusion. A useful future-work paragraph states a testable next step rather than promising unspecified improvements.

VII. CONCLUSION

Summarize the problem, your idea, and the conclusion supported by your evidence. End with a specific direction for future work.

Connect the main finding to the research question introduced at the start of the paper. Explain what the completed work adds to the reader’s understanding and which assumptions limit that interpretation. Distinguish demonstrated outcomes from expected benefits. Identify one concrete next study that would strengthen or challenge the conclusion, and explain why that study matters. Avoid introducing new results or unsupported claims here.
